

Canine Cesarean Section – Post-Operative Instructions

A cesarean section or c-section is major surgery performed to remove puppies from the uterus. Most dogs recover quickly from this procedure; however, if your dog was in labor for several hours before surgery was performed, her recovery will be slower, and she will need extra attention and help with her litter.

What should I expect during the mother's recovery period?

The mother has been given an anesthetic that will be eliminated from her body quickly. Most dogs have fully recovered from anesthesia by the time they arrive home. Complete recovery from anesthetic may take two to six hours, depending on the mother's physical condition and age at the time of surgery.

During the immediate recovery period, she must be restrained so that she does not fall and hurt herself or roll over and crush the puppies. The puppies should not be left alone with her until she is completely awake and able to stand on her own.

The mother should begin eating within a few hours after she is completely awake. Encourage her to eat and drink all that she wants, being careful that she does not overload her stomach by eating too quickly. This can result in vomiting. Her food intake at this time should be about one-and-a-half times her normal food intake. By the third or fourth week of nursing, her food intake may be two to three times normal.

The mother's temperature may rise 1°-2°F above normal the first one to three days after delivery, then it should return to the normal range. The normal range is 100°-102°F (37.8°-38.9°C). Your

dog should not be given aspirin or other medications without consulting your veterinarian. If the mother's temperature goes above 104°F (40°C), she and her litter should be examined by your veterinarian.

When should the puppies begin to nurse?

The puppies should be ready to nurse as soon as you arrive home. Although the mother may not be awake enough to nurse the puppies alone, you can assist by making the mother lie still so the puppies can nurse.

If the mother does not have any milk at first, you may supplement the puppies with milk replacer for the first day or two. There are many good commercial canine milk replacers available. Nursing bottles are available, made in the appropriate size for the puppies' tiny mouths. The following formula may be used for a day or two if the other products are not available:

1 cup milk + 1 tablespoon corn oil + 1 pinch of salt + 3 egg yolks (no whites). Blend together until uniform. It should be fed at the rate of 1 oz (30 ml) per 1/4 lb. (1/8 kg) of puppy weight PER 24 HOURS. That amount should be divided into 3-5 feedings. The average newborn, small breed puppy weighs approximately 1/4 lb. (1/8 kg) at birth.

Although we prefer that puppies begin nursing immediately, a healthy newborn can survive nicely for up to twelve hours without nursing. However, if the newborn is weak, dehydrated, or chilled, nourishment must be given as soon as possible.

How warm should we keep the room where the puppies are?

A newborn puppy is not able to regulate its body temperature very well; they can only maintain their body temperature at 15 degrees above room temperature. As long as the puppies stay near their mother, the room temperature is not too critical. However, if they are not with their mother, their immediate environment should be between 85°-90°F (29.4°-32.2°C). If the litter is kept outside, chilling or overheating is much more likely to occur. The newborns should be kept inside the house if possible.

Is a bloody vaginal discharge normal?

A bloody vaginal discharge is normal for three to seven days following birth. It may be quite heavy for the first one to three days after delivery and then begin to diminish. If it continues for longer than one week, the mother should be checked for the presence of infection. If she was spayed at the time of the surgery, there should be no vaginal discharge.

What does it mean if the puppies are crying frequently?

Puppies should sleep or be nursing 90% of the time. If they are crying or whining, something may be wrong. Uterine infections, inadequate quantity of milk, poor-quality milk, and infected milk are the most likely causes. The entire litter can die within twenty-four hours if one of these occurs. If you are not comfortable with the way the litter is doing, the puppies and the mother should be examined by your veterinarian.

When are her stitches removed?

The stitches may or may not need to be removed, depending on the type of suture material used. As a general rule, if the stitches are visible, they will have to be removed. Removal should occur at ten to fourteen days after surgery.

When should the puppies be weaned?

Weaning should begin when the puppies are about three to four weeks old. The first step is to place a 50:50 mixture of water and milk replacer or milk in a flat saucer. The puppies' noses should be dipped in this mixture two to three times per day until they begin to lap. Once lapping

begins, a canned puppy food should be crumbled in the water: milk mixture. As they begin to eat the solid food, the water: milk mixture should be reduced until they are eating only the solid food. Once they are eating solid food (usually about six weeks of age), the puppies may be placed in their new home. However, it is much better if the puppies remain with their mother and littermates for the first eight to ten weeks to fully socialize. This may decrease the incidence of behavioral problems caused when the puppies are removed from the litter too early.

When are the puppies treated for worms?

Puppies can be treated for worms when they are three and six weeks of age. It is important that accurate weights are obtained for the puppies so that the proper dose of medication can be used.

When should vaccinations begin?

First vaccinations typically begin at six to eight weeks of age. If your puppies were not able to nurse during the first three days of life, they will not have received proper immunity from their mother's first milk or *colostrum*. In this situation, vaccinations should begin earlier. Your veterinarian will discuss with you when it is appropriate for your puppies to be vaccinated.
